

Promoting Peace Amid Group Conflict: An Intergroup Contact Field Experiment in Nigeria

Christopher Grady, Rebecca Wolfe, Danjuma Dawop, and Lisa Inks

September 16, 2020

Abstract

Cooperative intergroup contact, originally designed as a tool for prejudice reduction, offers a promising means to resolve group conflict. Evidence for contact-based interventions is sparse, however, and violent conflict may nullify the effects of contact. We test the ability of a contact-based intervention to promote peace between conflicting groups with a field experiment in Nigeria, where farmer and pastoralist communities are embroiled in a deadly conflict over land use. We evaluate the program with surveys, direct observation of behavior in markets, and a behavioral game. We find that participation in the program increases intergroup trust, feelings of physical security, and voluntary intergroup contact measured both with self-reports and observed behavior in markets. Many of the program's effects also diffuse to group members who did not directly participate in the program but who lived alongside participants. The program had no effect on a placebo outcome, attitudes towards violence, that one would expect to improve if the survey results were affected by social desirability bias. These results suggest that reducing barriers to peace between conflicting groups is possible, and that structured intergroup contact is a promising method to do so.

Thanks to Jake Bowers, Jim Kuklinski, Justin Rhodes, Cara Wong, Caglayan Baser, Ekrem Baser, Nuole Chen, Alice Iannantuoni, Betsy Rajala, Charla Waeiss, and Donald Beaudette for useful conversations and feedback on earlier drafts of this paper. Thanks to Danjuma Dawop, Lisa Inks, Rebecca Wolfe, and the Mercy Corps Nigeria team for their work implementing the peacebuilding project. Thanks to Tahiru Ahmadu, Ibrahim Hassan, and the enumeration teams for their excellent work interviewing farmers and pastoralists. Thanks to Hadiza Nuhu and Israel Okpe for their work as the main contact people and mobilizers in farming and pastoral communities.

1 Introduction

How can groups in conflict improve intergroup relations? Violent group conflict has caused 2 million deaths since the year 2000 (Sundberg and Melander 2013), forcibly displaced over 70 million people from their homes in 2018 (UNHCR 2019), threatens food supplies in numerous countries (Verwimp and others 2012), and extracts a psychological toll on participants and victims (Rigterink and Schomerus 2019). Intergroup animosity perpetuates conflict long after the original grievance is immaterial or forgotten (Deutsch 1973; McDonnell 2017; Tajfel and Turner 1979), so improving intergroup relations is vital to stem the human, economic, social, and psychological costs of violent group conflict.

Scholars and practitioners consider *cooperative* intergroup contact – contact in which members of two groups work together to achieve common goals – to be one of the most effective tools for improving intergroup relations.¹ Evidence for the hypothesis that contact improves intergroup relations, known as the contact hypothesis (Allport 1954), goes as far back as the 1950s and motivated integrated public housing (Deutsch and Collins 1951) and workplace and school desegregation (Cook 1985; Cook, Wrightsman, and Wrightsman 1971; Slavin and Cooper 1999) in the United States. More recent studies demonstrated the prejudice-reducing effects of contact by leveraging or initiating random assignment to college dorms (Marmaros and Sacerdote 2006), college roommates (Boisjoly et al. 2006; Burns, Corno, and La Ferrara 2015; Van Laar et al. 2005), schools (Rao 2019), medical doctors (Weiss 2019), U.S. Air Force groups (Carrell, Hoekstra, and West 2015), mixed sports teams (Ditlmann and Samii 2016; Lowe 2020; Mousa 2020), job training programs (Scacco and Warren 2018), and cross-group discussions (Chang and Peisakhin 2019; Paler et al. 2020). The contact hypothesis also increasingly motivates policy interventions, especially peacebuilding programs (Ditlmann, Samii, and Zeitzoff 2017; Lemmer and Wagner 2015).

Despite contact's many successes, scholars have only just begun to implement and analyze contact-based interventions in conflict and post-conflict settings, to mixed results.² Some studies, like Mousa (2020) and Scacco and Warren (2018), find that contact interventions in these settings have no impact on attitudes towards the other side but may affect some cooperative behaviors. Others, like Weiss (2019) and Ditlmann and Samii (2016), suggest that contact in these settings can improve attitudes. We contribute our study of an eighteen month contact-based peacebuilding intervention involving communities and individuals who are participating in a violent conflict. We measure effects on attitudes and behaviors not only on individuals who directly participate in the contact program, but also on other individuals in their communities. If cooperative contact is to improve relations between groups amid ongoing conflict, then effects of contact-based interventions must diffuse from group members who participate in the interventions to individuals who do not.

Improving group relations through intergroup contact amid violent group conflict faces many challenges. The mechanisms through which contact improves individuals' negative attitudes assume that negative attitudes result from unfamiliarity, and that "familiarity breed[s] liking" (Pettigrew and Tropp 2006, 766). We posit that cooperative contact to achieve a common goal provides positive cross-group interactions and makes shared interests salient. Positive interactions and awareness of shared interests counter existing negative beliefs and create cognitive dissonance (Festinger 1962; Tavis and Aronson 2008). Attitudes improve when that cognitive dissonance is resolved by rejecting negative beliefs rather than justifying negative beliefs (Gubler 2013). Other group members' attitudes improve through new cooperative norms and through awareness of positive interactions and shared interests (Christ et al. 2014; Wright et al. 1997). Ongoing

¹We will use the term *cooperative contact* to refer to contact that meets Allport's conditions. Those conditions are (1) intergroup cooperation (2) with equal status (3) to achieve shared goals (4) with support of local authorities. Note that *equal status* does not mean that the groups must have the same status in society, but that the groups share equal status in the cooperative situation. Cooperative contact stands in contrast to other forms of incidental or unstructured contact that may not have positive effects on intergroup relations (Enos 2014).

²More generally, there are even a dearth of interventions directed at improving adults' attitudes towards racial or ethnic groups (Paluck, Green, and Green 2019).

violence, by reinforcing negative beliefs and obscuring shared interests, could dull, prevent, or even reverse the predicted positive effects of contact.

To learn about whether cooperative contact can improve intergroup relations amidst violent group conflict, we conducted a field experiment with conflicting farmer and pastoralist communities in Nigeria. More than an occupational difference, farmers who cultivate crops and pastoralists who graze cattle define a major social cleavage in many parts of the world. These groups fight over land rights, which define both of their livelihoods. Farmer-pastoralist conflict has escalated throughout the Sahel in recent years, and nowhere more than in Nigeria. The most recent conflict escalation has caused 7,000 deaths from 2014-2019 and displaced hundreds of thousands of people from their homes; The scale of economic damage is unknown, but farmer-pastoralist conflict *before* this escalation cost Nigeria \$13 billion annually in lost economic productivity (Akinwotu 2018; Daniel 2018; Harwood 2019; McDougal et al. 2015). In our sample, some members of each community had been killed by members of the other community in the year before the project began. Ongoing violence, occupational, ethnic, and religious differences, and fighting over resources necessary for livelihoods all make this context a hard test for contact theory.

We randomly assigned communities with ongoing farmer-pastoralist violence to receive a contact-based intervention or serve as a control group. The intervention formed mixed-group committees and provided them with funds to build infrastructure that would benefit both communities; committees then collaboratively chose and constructed infrastructure projects.³ The program also provided mediation training to each community's leaders and held forums where the groups discussed the underlying drivers of conflict. We used survey and behavioral measures to assess the effects of the intervention, including pre- and post-intervention surveys, a post-intervention natural public goods behavioral game,⁴ and twelve months of systematic observations in markets and social events during the intervention.

We find that the program increased intergroup affect, intergroup contact outside of the intervention, and perceptions of physical security, though it did not increase contributions in the public goods game. We see signs of positive effects in fieldwork as well as in data: in one of the treatment sites, farmers defended pastoralists from a group of anti-pastoralist vigilantes, rather than assist the vigilantes in removing the pastoralists and claiming their land. Our results also show that the intervention affected communities as a whole, not just community members directly involved in the intergroup contact. Individuals who directly engaged in intergroup contact changed the most positively from baseline to endline, but we also observe positive spillovers to group members for whom we did not exogenously increase intergroup contact. These changes are unlikely due to social desirability bias – we observe no differences on a placebo outcome that should be affected by social desirability but not the intervention.

This study expands our knowledge about intergroup contact and group conflict in two main ways. First, this study teaches us about the capacity of intergroup contact to improve intergroup relations during a violent conflict. Peacebuilding organizations implement numerous contact-based interventions in violent conflicts each year, but few studies evaluated these interventions' effects in conflict and post-conflict settings, and this study had evaluated these interventions' effects on the wider community who did not participate in the contact intervention. Influencing the wider community is necessary for contact interventions to be useful in reducing group conflict, and our results suggest that contact-based peacebuilding programs can effectively reach non-participants and improve relations between conflicting groups.

Second, this study brings evidence to the debate about whether contact interventions shift attitudes, behaviors, or both. Some contact interventions suggest contact affects some behaviors but not attitudes (Mousa 2020; Scacco and Warren 2018); others suggest contact affects attitudes but not behaviors (Paler et

³The communities built boreholes, market stalls, and primary health care facilities, for example.

⁴In a public goods game (PGG), research subjects are given money and told they can keep the money or donate it to a public fund. Money donated to the public fund is multiplied by some amount and then shared with all subjects. Our PGG is *natural* because it was conducted in a natural setting, rather than a lab. The funding for the PGG came from the National Science Foundation under Grant No. 1656871.

al. 2020); still others suggest contact affects neither (Chang and Peisakhin 2019). Our intervention suggests that contact can affect both attitudes and behaviors. We identify our intervention's duration and publicness as potential explanations for why we observe effects where others do not. Most contact interventions last a relatively short time and are contained to the participants and not broadcast to the larger community. Our intervention lasted eighteen months and the contact it organized could be observed by the wider community. Public interventions are more likely to affect attitudes and behaviors (Adida et al. 2020; Arias 2019; Grossman and Michelitch 2019) and we expect that they are also more likely to create norms that can diffuse to other community members.

2 Improving Intergroup Relations Through Cooperative Intergroup Contact

Cooperative intergroup contact has long been posited as a means to improve intergroup relations. Popularized by Gordon Allport (1954), the contact hypothesis assumes that negative stereotypes cause intergroup animosity. Stereotypes, natural mental shortcuts that help an individual understand his/her experiences, are especially likely to go awry and create animosity when an individual has little or no experience with members of another group. Without intergroup experience, stereotypes will misrepresent groups, create imagined differences between ingroup and outgroup members, and obscure shared interests. To remove these negative stereotypes new experiences must override them, allowing an individual to re-conceptualize the outgroup.

Allport and subsequent authors specified four conditions under which contact will remove stereotypes and improve intergroup relations. First, the contact must involve ongoing personal interaction between members of both groups. Second, both groups must have equal status in the interaction. Third, the interaction must involve cooperation towards a common goal. And fourth, the intergroup interaction must have the support of, or at least not be punished by, institutions and authorities. These conditions ensure positive interactions between group members.

Allport argued that contact works by enhancing knowledge and overriding negative stereotypes about the outgroup, and subsequent scholarship has identified three additional mechanisms through which contact improves attitudes. First, contact reduces the feelings of threat and anxiety that arise from fear of the unknown (Page-Gould, Mendoza-Denton, and Tropp 2008; Stephan and Stephan 1985). Second, contact enables perspective-taking so that ingroup members empathize with the outgroup (Batson et al. 1997; Broockman and Kalla 2016). And third, contact makes salient a shared identity based on the groups' similarities and interests (Gaertner and Dovidio 2014; Gaertner et al. 1993). Through these mechanisms group members can experience positive cross-group interactions, which triggers cognitive dissonance against the preexisting negative attitudes. Attitudes improve when that dissonance is resolved by rejecting, rather than justifying, negative attitudes towards the outgroup (Gubler 2013).

These mechanisms support the reduction of group-based prejudice for individuals involved in the intergroup interaction, but the positive effects of contact must diffuse to individuals not involved in the interaction for intergroup contact to meaningfully improve intergroup relations. This diffusion to other group members can occur through changing social norms about cross-group interaction (Christ et al. 2014; Paluck 2009) and through the knowledge that other ingroup members had positive contact with outgroup members (Wright et al. 1997). Norms and awareness of cross-group cooperation shows that cross-group interaction is safe and socially encouraged. It also creates the expectation of future interaction with outgroup members, which motivates individuals to see the outgroup more positively (Klein and Kunda 1992; Van Dessel, Hughes, and De Houwer 2019). Through social diffusion cooperative contact improves attitudes even for ingroup members with no cross-group contact.

Taken together, the existing literature suggests that cooperative contact improves intergroup relations through four steps. First, cooperative contact provides positive interactions that remove the psychological barriers – negative stereotypes, feelings of outgroup threat, and a lack of empathy – that bias perceptions of the other side. Second, without these perceptual biases groups can identify shared interests, and cooperative

contact facilitates the identification of shared interests by having the groups cooperate towards a common goal. Third, positive interactions and the identification of shared interests challenge pre-existing negative beliefs and trigger cognitive dissonance. Attitudes improve when that dissonance is resolved by rejecting preexisting negative attitudes in lieu of new positive experiences. Fourth, positive attitudes diffuse to other group members through awareness of cross-group cooperation and changing social norms.

2.1 Cooperative intergroup contact the context of violent group conflict

Violent group conflict poses a  test for cooperative intergroup contact to improve attitudes. First, in the context of ongoing violent conflict, even cooperative contact towards a joint goal may not provide group members with a subjectively positive cross-group interaction. Due to psychological biases, individuals perceive cross-group interactions negatively so that those interactions conform to pre-existing beliefs; individuals also more readily store and recall negative interactions that confirm pre-existing attitudes than positive interactions that are dissonant with pre-existing attitudes (Nickerson 1998; Ward et al. 1997). If individuals perceive cooperative contact negatively, contact could make attitudes worse, not better (Barlow et al. 2012; Paolini, Harwood, and Rubin 2010; Stark, Flache, and Veenstra 2013).

Even if contact succeeds in providing positive experiences with outgroup members, the resulting cognitive dissonance may not be resolved by embracing positive attitudes. Participation in and victimization by violence motivates group members to justify their existing attitudes (Kunda 1990). Existing attitudes are harder to reject once an individual has acted on them (Festinger 1962; Tavis and Aronson 2008). Once an attitude is acted upon, rejection of the attitude threatens an individual's self-identity because the individual must come to terms with his or her own immoral behavior. Likewise, individuals are less likely to reject existing attitudes when they have personal experiences that reinforce those attitudes. In the case of prejudice, prejudiced attitudes are least likely to be rejected when an individual has harmed or been harmed by the outgroup. Instead of rejecting negative attitudes, violent experiences can lead individuals to resolve cognitive dissonance by justifying previous attitudes (Gubler 2013) or, at best, by differentiating "good" outgroup members from typical outgroup members (Doosje, Spears, and Koomen 1995).

Beyond past violence, ongoing group violence provides negative experiences with outgroup members that counter the positive experiences provided by cooperative contact. These negative experiences bolster the psychological barriers to groups' identifying their shared interests. Rather than dispelling stereotypes and alleviating feelings of threat, negative experiences reinforce negative stereotypes and justify feelings of threat. Taking the perspective of the other side will not improve cross-group relations if taking their perspective reveals incentives for belligerence (Kertzer, Brutger, and Quek 2018). And far from revealing common identities and interests, group violence perpetuates opposing group identities and interests (Fearon and Laitin 2000). To overcome preexisting negative beliefs, individuals need strong and consistent information that counters those existing beliefs – a signal that the object of their belief has changed (Nickerson 1998). For that reason, some scholars believe group reconciliation cannot begin until conflict is resolved (Bar-Tal 2000).

Social norms are a potent means to change attitudes and behavior, but in contexts of group violence social norms may prevent rather than facilitate attitude change (Bar-Tal 2007; Bar-Tal and Avrahamzon 2017). These pre-existing norms self-perpetuate by discouraging ingroup members with positive attitudes from displaying those attitudes, either through talking about or engaging in cross-group interaction publicly. Group members who do not conform to these norms risk being branded as traitors (Bornstein 2003). With no opportunities to hear about or observe positive cross-group interaction, the effects of contact cannot extend to ingroup members without contact.

But these barriers do not mean that contact cannot improve intergroup relations for groups in violent conflict. Conflicting groups share an interest in obtaining peace because fighting is costly (Fearon 1995), and cooperative contact can make that shared interest in peace salient. Though existing norms likely support negative attitudes, successful cross-group cooperation can generate cooperative social norms because cooperation and peace are in the interest of both groups. Cooperative contact also shows that the outgroup

is composed of differentiated individuals (Rimé et al. 2011), opening the possibility that past negative experiences with a few outgroup members do not characterize the entire outgroup.

3 Farmer-pastoralist conflict in Nigeria's Middle Belt

Nigeria's Middle Belt is plagued by violent conflict over land use. Farmers, who claim land for agricultural production, and pastoralists, who claim land for animal grazing, increasingly clash over claims to the same land. Both groups depend on land for their livelihoods, but their divide is also cultural, ethnolinguistic, and, in some locations, religious. The pastoralists are almost homogeneously of the Fulani ethnic group, speak Fulfulde as their primary language, and practice Islam. They maintain a semi-nomadic way of life, belonging to a home community but traversing vast distances to secure access to pastureland and water as seasons change. The farmers live in sedentary villages and exploit land for agriculture. The ethnic group, language, and religion vary by village. In our study, farmers came from more than a dozen ethnic groups, often residing side by side.

Historically, these communities cooperated through trade and sharing land that was abundant relative to populations. Pastoralists would graze their animals on crop residue after harvests and follow migration paths away from farmland during planting seasons. The groups were complementary: pastoralists gained food for their animals and farmers gained animal manure/urine to replenish soil; farmers bought milk and meat from pastoralists and pastoralists bought grains and vegetables from farmers. There were tensions, but these were typically overcome by negotiation and violence seems to have been rare. The Middle Belt came to be known as Nigeria's  "food basket" due to the abundance of foodstuffs coming out of the region, like beef, dairy, yam, and cassava.

In recent years, this relationship has been stressed by populations' booms and climate change. Nigeria's population at independence in 1960 was about 50 million; Nigeria's population in 2019 is estimated around 200 million. At the same time, the Sahara's size expanded over 10%, decreasing land available for farming and grazing (Okpara et al. 2015; Thomas and Nigam 2018). As the number of farmers, pastoralists, and mouths to feed increased, the amount of land available to produce food declined. These factors also pushed pastoralists southward, towards farming communities with whom the pastoralists had no pre-existing relationship. Land scarcity and new migrants jeopardize traditional cooperative agreements that have managed farmer-pastoralist interactions for decades (Cotula et al. 2004; Kuusaana and Bukari 2015). Sharing land is easier when people are scarce and land is plentiful; it is not so easy when land is scarce and people are plentiful.

Government policies exacerbated the issues caused by demographic and geographic changes. Land privatization encouraged farmers to plant crops that occupy land continuously, like orchards, and effectively nullified farmer-pastoralist land sharing agreements (Bassett 2009). Official cattle reserves for moving herds are rarely enforced by the government, leading farmers to plant crops in once-protected areas and further limiting pastoralists' available grazing space. The "indigene versus settler" policy limits economic and political rights to certain ethnic groups in each state, often denying the "settler" pastoralists the ability to own land and run for political office (Network 2014).

These stressors have sparked violent conflict between farmers and pastoralists in recent years (Ilo, Ier, and Adamolekun 2019). The most recent conflict escalation, beginning roughly in 2014, has caused 7,000 deaths (Harwood 2019) and displaced hundreds of thousands of people from their homes (Akinwotu 2018; Daniel 2018). The scale of economic damage is unknown, but farmer-pastoralist conflict *before* this escalation cost Nigeria \$13 billion annually in lost economic productivity (McDougal et al. 2015). This violence has impeded food production, leading to an impending food crisis  2018; Ilo, Ier, and Adamolekun 2019; Unah 2018). Compounding matters, state government  response to  conflict has been to enact anti-grazing laws. These laws spark more violence because many pastoralists ~~reasonably~~ viewed

⁵<https://qz.com/africa/1315749/nigeria-herdsmen-farmer-attacks-are-damaging-agriculture-economy/>

the law as biased against their way of life. In the state of Benue, the government mobilized state-sanctioned vigilante groups called “livestock guard” to enforce the law, but the livestock guard have sometimes fought out pastoralists, rather than guard farmland (Duru 2018).

Though we have discussed the conflict as between two large and cohesive groups (“Farmers” and “Pastoralists”), the conflict occurs between numerous small, independent farming and pastoral groups. The groups typically reside a couple miles from each other – like people from the next town over. These independent groups are aware of the broader context of farmer-pastoralist conflict, but their concerns are local and mostly unrelated to what happens in distant villages. Different versions of the same story initiate and sustain the local conflicts. First, cattle graze on farmland.⁶ Next, a farmer retaliates by stealing cattle from the pastoralists (because the farmer does not know *which* herd grazed on his land, the stolen cattle do not necessarily come from the transgressing herd). This cycle continues and eventually explodes when a member of one side physically attacks a member of the other side. From there, a little war often breaks out. As one reporter noted, “The countryside is littered with the charred ruins of homes, schools, police stations, mosques and churches.” (McDonnell 2017).

Farmer-pastoralist conflict poses a tough test for intergroup contact to improve group relations. The material, social, and psychological incentives of these groups are opposed. They want the same land for different purposes and their livelihoods depend on that land. The groups are involved in a bloody, violent, and escalating conflict for land in which thousands of farmers and thousands of pastoralists have been killed by members of the other group. Within an individual’s community, several people will have been attacked or killed; several others will have attacked or killed members of the other side. To justify killing, groups create collective myths about the retaliatory/defensive nature of their belligerent action and the iniquity and inhumanity of the other side. Despite their physical proximity, the groups have little to bond over; they are distinct culturally, ethnically, linguistically, and often religiously. And finally, government favoritism of farmers over pastoralists creates a power disparity between the groups.

Despite the forces pushing these groups into conflict, their interests are not completely misaligned. Peace is in the interest of both groups because fighting is costly, both materially and psychologically. The conflict has destroyed billions of dollars in agricultural produce, animal products, and physical infrastructure. Crops have been destroyed, cattle stolen, homes burned, and neighbors murdered. Farmers fear violence when working in their fields; pastoralists fear violence when grazing their cattle. Peace can end the economic, social, and human costs. Moreover, the groups formerly maintained mutually beneficial trade agreements: farmers trade the crop residue left on their fields for animal manure/urine to replenish soil; farmers traded grains and vegetables in exchange the pastoralists’ milk and meat. Peace rekindles the possibility of these mutually-beneficial trade agreements. Cooperative intergroup contact should improve group relations by making salient these shared interests.

3.1 Intervention: Engaging Communities for Peace in Nigeria

To address farmer-pastoralist conflict, ~~humanitarian and development~~ INGO Mercy Corps implemented a two-year, USAID-funded program titled Engaging Communities for Peace in Nigeria (ECPN) in Middle Belt sites embroiled in violent conflict. The main objective of the program was to foster positive contact between farmers and pastoralists, improve attitudes, improve intergroup relations, and ameliorate conflict. Mercy Corps implemented the project in two Middle Belt states, Benue and Nassarawa, which have been focal points for farmer-pastoralist conflict.

The intervention formed mixed-group committees with equal numbers of farmers and pastoralists and provided them with funds to build infrastructure that would benefit both communities; committees then collaboratively chose and constructed infrastructure projects. It started with separate farmer and pastoralist

⁶In past decades, compensation for crop damage would have been standardized, but these traditional agreements have fallen apart in recent years (Cotula et al. 2004; Kuusaana and Bukari 2015). With no agreed upon compensation and no authority to punish illegal grazing or illegal cattle rustling, groups take justice into their own hands.

community meetings to avoid negative contact experiences. These intra-community meetings eventually led to joint decision-making meetings with the two groups together. Each joint project committee included an even number of farmers and pastoralists, as well as women and youth representatives, and totaled between 12 and 16 members. Each committee received two grants, one for quick-impact projects, of approximately \$2,000, and one for joint projects, of approximately \$25,000.

The quick-impact projects were conceived as a trust-building initiative, intended to let community members see that cooperation was possible. Projects, managed by both farmers and pastoralists, included hand pumps; construction or rehabilitation of market stalls, schools, and health centers; and construction of fences along grazing routes to protect farmlands and avoid accidental crop damage. The joint economic development projects aimed to address an underlying issue related to the conflict: sharing of resources that impact livelihoods. Pollution of water, affecting both farming and livestock, was the primary issue people raised. As a result, each site chose to build a new borehole well, with members of both farmer and pastoralist communities helping to construct the wells.

To ensure support of authorities, the program involved community leaders from both sides in all aspects of the project. They were involved in the quick-impact projects and joint economic development projects. Mercy Corps also provided mediation training to each community's leaders and held forums where the groups discussed the underlying drivers of conflict.

These projects were designed with the conditions of Contact Theory in mind. Groups (1) cooperated with (2) equal status to achieve (3) shared goals with (4) support of local authorities. These projects were meant to help the groups solve, through intergroup cooperation, problems relevant to both groups. This would reveal to groups that they shared many of the same struggles and that cooperation could help them overcome these struggles.

In the next section we describe the research design to determine the effects of intergroup contact on intergroup attitudes and behaviors.

4 Research Design

We evaluate the effects of Engaging Communities for Peace in Nigeria (ECPN) with a site-level field experiment. Each site contains two communities, one of farmers and one of pastoralists. The communities within a site engaged in deadly clashes within one year of our scoping exercise.⁷ We identified fifteen sites eligible for the study and surveyed ~50 randomly selected respondents per community. We then randomly selected the communities in ten of fifteen sites to receive the intervention, blocking by state so that an equal proportion of sites in Benue and Nassarawa received the program. After 18 months, we surveyed another ~50 randomly selected respondents and ~10 respondents from the baseline survey per community. In between the surveys, we monitored farmer-pastoralist interactions in markets and at social events.⁸

This design gives us two datasets to analyze. First, we aggregate the randomly-sampled individuals to compare communities before and after the intervention. The main goal of this analysis is to learn about the effect of implementing ECPN in a community. Communities were randomly assigned to receive the intervention or function as a control group, which allows us to determine the causal effect of the intervention at a community-level. This comparison between communities that received or did not receive the intervention is our main analysis.

Second, we supplement the community-level analysis by creating a dataset of ~10 respondents per community before and after the intervention. The main goal of this analysis is to learn about the effect of

⁷To identify eligible sites, we undertook a scoping exercise to determine if the two communities in an implementation site had a demonstrated need for a peacebuilding program and were willing to participate in one. We defined “demonstrated need” as the communities engaging in violent clashes within one year of the scoping exercise. Willingness to participate in the program was obtained through conversations with community leaders, none of whom refused the program.

⁸This experimental design was pre-registered with Evidence in Governance and Politics (EGAP) under ID 20150716AA. The preregistration can be found at <http://egap.org/registration/1242>.

participating directly in ECPN committees, and thus directly experiencing intergroup contact, relative to the effect of living in communities where ECPN was implemented but not participating in committees, and thus only experiencing indirect intergroup contact. From our baseline random sample, we identified and resurveyed (1) ECPN committee participants, (2) respondents who lived in intervention sites but did not participate in ECPN committees, and (3) respondents from the control group, who neither participated in ECPN committees nor lived in communities where ECPN was implemented. We then compare the change of participants and nonparticipants in intervention sites to the change in control respondents. Our ability to make generalizable causal claims about participation is limited, though, because individuals in intervention sites were not randomized into participation  nonparticipation with ECPN committees.⁹

In total, we randomly sampled 1557 respondents at baseline in 2015. 1027 of those respondents were in intervention sites and 512 were in control sites. At endline, we resurveyed 287 of those respondents. 74 of those respondents directly participated in ECPN, 121 were in intervention sites but did not participate, and 92 were in control sites. At endline, we also randomly sampled 1523 respondents, 1028 in intervention sites and 495 in control sites.

4.1 Estimation

Here we describe our estimation procedure for the community-level analysis and the individual-level analysis. For both analyses we estimate one-tailed tests because our hypotheses are that the change in outcomes for treatment units will be *greater than* control, not that the change in outcomes for treatment units will be *different* than control.¹⁰ Both analyses also use randomization inference for p -values and bootstrapping for standard errors. The specifics of each procedure are described in Appendix A.

We use two estimators to estimate the treatment effect of the intervention. When treatment groups are balanced on the baseline outcome, we use the baseline outcome as a covariate to predict the endline outcome, as seen in equation 1. When treatment groups  not balanced on the baseline outcome, we use the change score of the outcome as Y , as seen in equation 2.

$$Y_{i,j} = \beta_0 + \beta_1 Z_{i,j} + X_{i,j} + \delta_j + \epsilon_{i,j}$$

Where i is the community in state j , Z is the treatment indicator, X is the outcome at baseline, and Y is the outcome at endline. δ is a fixed effect for the state j in which the community belongs.

$$Y_{i,j} = \beta_0 + \beta_1 Z_{i,j} + \delta_j + \epsilon_{i,j}$$

Where i is the community in state j , Z is the treatment indicator, and Y is the change in outcome from baseline to endline. δ is a fixed effect for the state j in which the community belongs.

We use randomization inference for p -values and bootstrapping for standard errors because our units of analysis, communities and individuals, are clustered in sites and we have only fifteen sites. Analytic standard errors may underestimate the uncertainty of our causal estimate. Bootstrapping yields a distribution of possible treatment effects given the observed data, and the 95% confidence interval is between the coefficients at the 2.5th percentile and the 97.5th percentile.

4.2 Outcomes

We measured three outcomes to estimate the effect of the intervention: (1) intergroup attitudes, (2) intergroup contact, and (3)  insecurity. If the intervention improved intergroup relations, we would expect

⁹We initially randomly assigned baseline survey respondents to be part of ECPN committees, but random assignment proved difficult. Many people who were not selected wanted to be on the committees, and some people who were selected were not able to participate or could not be located when the committees were launched. As a result, people self-selected into committees.

¹⁰Note that for one-tailed tests, p -values above 0.50 indicate that the coefficient moved in the opposite direction of the alternative hypothesis.

¹¹We use two different equations because the effectiveness of each equation depends on the correlation between treatment assignment and baseline outcomes. The “controlling-for” method of equation 1 is more precise but is biased when treatment assignment correlates with baseline outcomes. The “differencing” method of equation 2 is unbiased but less precise. For a comparison between these methods, see <https://declaredesign.org/blog/2019-01-15-change-scores.html>.

respondents to report better attitudes towards the outgroup, more intergroup contact and willingness to engage in intergroup contact, and reduced insecurity due to violence. We also measured a placebo outcome that may be affected by social desirability but should not be affected by the intervention: attitudes about violence. We measured these outcomes with survey self-reports, survey experiments, a natural-field behavioral game, and monitoring of farmer-pastoralist interaction in markets and social events.

For most survey self-reports, we combine together several survey questions to create an index. We create both additive indices and inverse-covariance weighted indices. Inverse-covariance weighting constructs an index by down-weighting index questions that are correlated with other index questions and up-weighting those that are uncorrelated with other questions. This approach maximizes the amount of unique information the index takes from each question and prevents “double counting” when two questions measure the same underlying concept. We report results using inverse-covariance weighted indices, but results hold with additive indices. Results with additive indices are included in Appendix B.

4.2.1 Primary outcome

Intergroup affect: Our first outcome is affect towards the other side. A primary goal of our contact intervention, and of much previous contact research, was for individual’s attitudes to improve. Changing attitudes towards the other side is one pathway towards improving intergroup relations and changing behavior, though not the only pathway (Paluck 2009; Scacco and Warren 2018).

We measure intergroup affect with survey self-reports and an endorsement experiment. The survey questions include two measures of intergroup trust and a five item social distance scale created for the farmer-pastoralist context.

In an endorsement experiment, respondents are asked how much they support a hypothetical policy. In the treatment condition, the policy is ‘endorsed’ by a group that the respondent has a positive or negative opinion about. In the control condition, the policy is not endorsed by any group. The average difference in support between the endorsed and unendorsed policy represents the change in support for the policy because of the group’s endorsement. In our case, we asked respondents how much they would support a water policy if it was endorsed by a farmer organization (asked of pastoralists), if it was endorsed by a pastoralist organization (asked of farmers), or if no endorsement was mentioned (the control condition posed to both pastoralists and farmers). Support was measured on a 5-point scale, where high values indicated support and low values indicated opposition.

Intergroup contact: Our second outcome is intergroup contact that occurs outside of the intervention. Natural, voluntary intergroup contact provides behavioral evidence that farmer-pastoralist relations are improving. We measure intergroup contact with survey self-reports, monitoring of farmer-pastoralists interactions in markets and social events, and a survey experiment.¹²

The self-reports and behavioral observations tell us the descriptive change in intergroup contact. The survey self-reports ask if and how often the respondent interacted with the other group in the past month. The respondents are asked about interaction in markets, at public social events, in the respondent’s own home, at the home of a member of the other group, and in any other way. The responses are then ranked, scaled from 0-1, and combined into an index. The behavioral observations provide a measure of contact independent of response biases.

In the markets, we measured interactions related to buying and selling market goods, such as the number of farmer and pastoralist sellers present and the number of farmer and pastoralist buyers. We then create a farmers index and a pastoralist index to measure the presence of farmers and pastoralists in the market. At social events, we measured the number of members of the other group in attendance and the number who ate or drank anything¹³, both in absolute numbers and as a percentage of total attendees. We then create

¹²Much of the self-reports and the observations are overdispersed count data. We recode all count data as rank.

¹³Taking food or beverages at a social event is a sign of closeness and intimacy in these contexts. Casual attendees would not take food or beverages

measures for the number of farmers and pastoralists attending social events and the number of farmers and pastoralists eating at social events.¹⁴

A survey experiment, which we are calling the *percent experiment*, tells us about respondents' willingness to engage in contact. It asks respondents two questions about their willingness to interact with members of the other side. We asked respondents if they would (1) join a group and (2) live in a community with some percentage of the other group. The percentage is randomized between 5%, 25%, 50%, and 75%; the percentage is the same for those two questions but varies across individuals. We take the mean response so that a respondent saying yes to both is assigned a 1, a respondent saying yes to one is assigned a 0.5, and a respondent saying no to both is assigned a 0. These questions allow us to determine if treatment communities become more willing to interact with outgroup members and if treatment communities become less sensitive to higher proportions of the outgroup.¹⁵

Insecurity: Our third outcome is feelings of insecurity due to conflict. The end goal of the intervention is to reduce conflict between farmers and pastoralist. The disaggregated and diffuse nature of the conflict makes obtaining an accurate measure of violent conflict extremely difficult.¹⁶ Instead, we measured the effect that violent conflict has on individuals. We ask respondents if they avoid any areas during the day or night due to insecurity and if insecurity restricted them from engaging in various activities, such as grazing their animals, working on their farms, fetching water for their families, and working for wages. We combined these ten insecurity questions into an index, with high values indicating low perceptions of insecurity and low values indicating high perceptions of insecurity.

Intergroup Coordination: We used a natural-field public goods game to measure the ability of the groups to coordinate to achieve a common goal. If the intervention causes respondents to incorporate the former outgroup into their ingroup, then we expect those communities to better coordinate in a public goods game. Compared with lab-based behavioral games, whose choice-making situations are necessarily artificial, the choice-making situation of a natural-field game is akin to the choices people make in their lives (Harrison and List 2004; Winking and Mizer 2014). Because these communities often decide how to contribute to some public good, such as repairing a borehole or a market, we chose to use a natural-field public goods game (PGG) as a realistic behavioral measure of coordination.¹⁷

These designs and measurements put us in a strong position to identify effects if effects exist. First, we have data at the community-level and individual-level. If the two analyses show similar relationships, we can be more sure that those relationships are not spurious. Second, both community and individual-level analyses use a baseline/endline + control group design to differentiate a secular trend from a treatment effect. Many changes occurred in the social environment between the beginning and the end of the intervention that could change intergroup relations, such as the economic downturn in Nigeria and the anti-grazing law in Benue. By comparing the change in the treatment group to the change in the control, we are more certain that differences are due to the intervention and not other factors. Third, outcomes are measured using survey

¹⁴Observations were made in two periods: July 2016 – February 2017, immediately after the project commenced but before joint project committees convened, and September 2017 – December 2017, after project committees convened but before the endline survey began. Events that occurred February 2017 or earlier are baseline measurements; events occurring September 2017 or later are endline measurements.

¹⁵This experiment was based on a question from the General Social Survey (GSS) asking respondents if they would favor or oppose living in a neighborhood that was half white/black.

¹⁶Asking respondents to recount the number of violent events does not accurately measure the scale of the conflict because those answers are determined by the awareness and memory of the community members. Awareness of individual violent events is low because many of the violent events occur in fields and grazing routes far from the town center and residential areas. In addition, the intervention sought to increase awareness of violent events through its conflict forums. The type of event that all community members are aware of – large massacres, burning of homes, etc. . . – generally lead to the disintegration of both communities as community members flee the area fearing further violence or reprisals. These large-scale events are rare and none occurred in intervention or control communities during the study.

¹⁷This game is similar to the one implemented by Fearon, Humphreys, and Weinstein (2009) as part of a similar study on community-driven development in Liberia.

self-reports, survey experiments, a behavioral game, and monitoring of social behavior. If we observe similar relationships across multiple modes we can be more certain that the relationship is not spurious.

5 Results

Our major finding is that the intervention improved intergroup attitudes, spurred intergroup contact outside of the program, and reduced feelings of insecurity. The program had the largest impact on respondents who participated on ECPN committees, but the effect extended to respondents who did not participate with ECPN. We use coefficient plots to report average treatment effects in our community-level data and in our individual-level data. We also use coefficient plots to show differences between participants, nonparticipants, and controls in our individual-level data. All coefficient plots show bootstrapped 95% confidence intervals and standardized coefficients.

Figure 1: Effect of treatment assignment on outcomes in community-level and individual-level data. Points are average treatment effects versus control estimated using OLS. Lines are bootstrapped 95% confidence intervals. Solid lines are effects in the community-level data, dashed lines are effects in the individual-level data. The first set of effects concern intergroup affect; the second set concern voluntary contact; the last concerns insecurity. Effects in the figure are positive if the intervention improved outcomes and negative if it worsened outcomes.

Figures 1 and 2 shows the intervention's effect on all primary outcomes. Figure 1 shows the main analyses, where the solid lines are the community-level data and the dashed lines are the individual-level data. Figure 2 shows participants and nonparticipants compared to controls. From top to bottom, the outcomes are ordered to correspond with: (1) intergroup attitudes, (2) intergroup contact, and (3) insecurity. Some outcomes – observations in markets and at social events, survey experiments – are only possible in the community-level analysis.

Figure 2: Effect of treatment assignment on participants and nonparticipants. Points are average treatment effects versus control estimated using OLS. Lines are bootstrapped 95% confidence intervals. Solid lines are effects among participants, dashed lines are effects among nonparticipants living in treatment communities. Effects in the figure are positive if the intervention improved outcomes and negative if it worsened outcomes.

5.1 Intergroup Affect

The intervention bolstered intergroup affect in treatment communities. Compared to control communities, respondents in treatment communities report more trust in the other group and are more comfortable engaging in various relationships with the outgroup, such as trading goods and intermarriage. Intergroup affect as measured by the endorsement experiment also improves more in the treatment group than the control group, though the difference is not statistically significant at conventional levels.

Figures 3a and 3b show the descriptive change in affect for treatment and control communities. Affect in control communities decreased from baseline to endline, while intervention communities improved over the same time period. As measured by the endorsement experiment, affect declines in both treatment and control communities, but declines more in control communities. Both measures suggest that the intervention improved affect towards the outgroup.

(a) Descriptive change in community-level intergroup affect from baseline to endline. Red line is treatment site average, blue line is control site average. Moving up the Y-axis indicates improved affect between groups.

(b) Descriptive change in individual-level intergroup affect from baseline to endline. Red line is participant average, dark red line is nonparticipant average, blue line is control average.

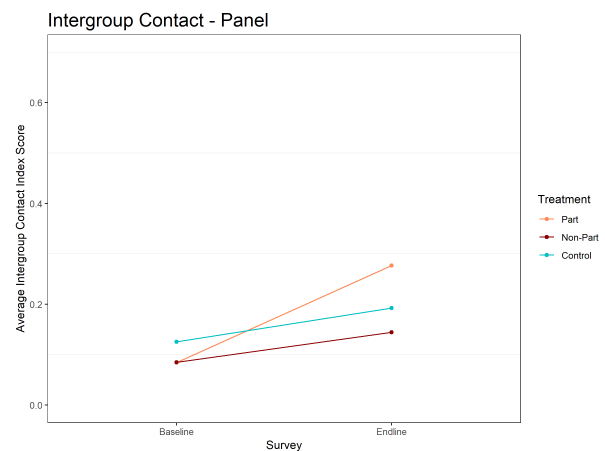

Figure 3: Intergroup Affect

5.2 Contact

The effect of the intervention on contact is substantial. Respondents in treatment communities report more contact and more willingness to engage in contact at all levels of the percent experiment; we also observe more pastoralists in markets interacting with farmers. Since the markets are all located in the farming community, the sustained presence of pastoralists there suggests that (1) farmers were accepting/tolerant of pastoralists in their community and (2) pastoralists felt comfortable spending time in the farmer community. The number of farmers present in the markets does not change in either group, which makes sense because the market is inside the farming community.

(a) Descriptive change in community-level voluntary contact from baseline to endline. Red line is treatment site average, blue line is control site average. Moving up the Y-axis indicates improved contact between groups.

(b) Descriptive change in individual-level voluntary contact from baseline to endline. Red line is participant average, dark red line is nonparticipant average, blue line is control average.

Figure 4: Voluntary Contact

Figures 4a and 4b show the descriptive change in contact for treatment and control communities. The community-level self-reports show that intergroup contact declined sharply in control communities but

rose slightly in treatment communities. The intervention was able to increase contact even as the social environment led to a sharp decline in control sites. At the individual-level, intergroup contact increased at the same rate for nonparticipants and controls but increased a great deal more for committee participants. This parallel relationship for nonparticipants and controls contradicts the large community-level effect, which suggested that the effects of the intervention extend to nonparticipants in treatment communities. One plausible explanation is that the effect on nonparticipants did not extend to the type of nonparticipant we could track down and resurvey; another explanation is that the type of control individual we could track down for resurveying increased their intergroup contact even as the rest of the community decreased theirs.

5.3 Insecurity

The intervention substantially decreased feelings of insecurity in the treatment group. The effect is large in both the community-level and the individual-level data. Security in treatment communities improved far more from baseline to endline than in control communities. At the individual-level, participants and nonparticipants improved equally, suggesting that these increases reflect a change in the conflict environment that impacts the entire community, not just respondents involved in ECPN committees. These improvements in treatment communities are especially powerful because other survey questions show that the intervention increased awareness of the conflict – respondents in treatment communities are more likely than the control to know that violence between groups has occurred recently, yet they feel more secure.

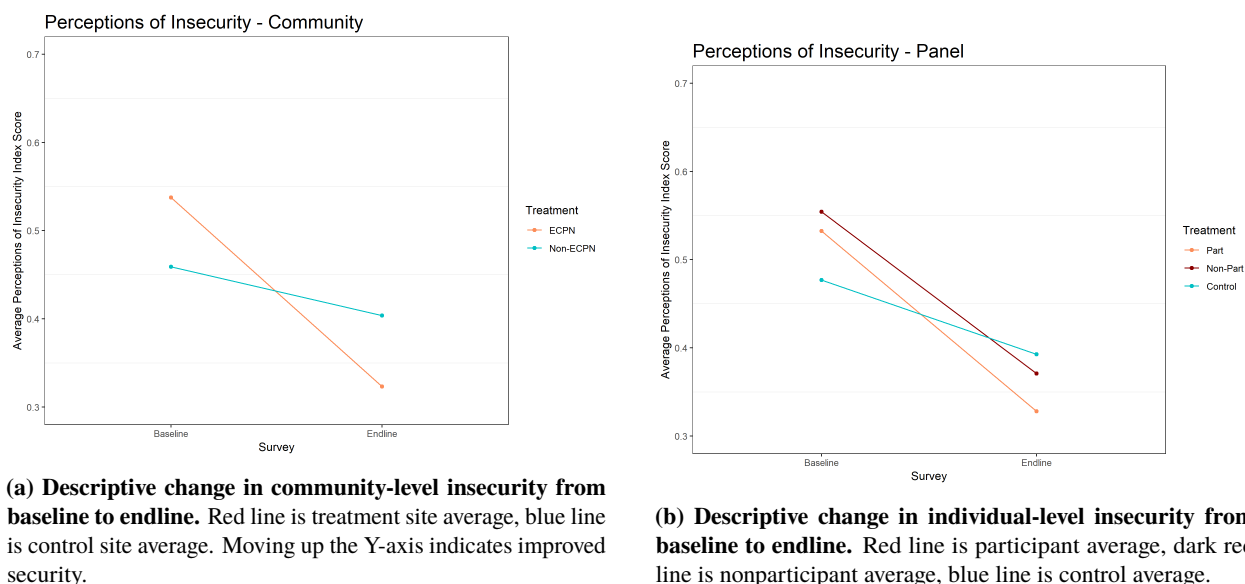

Figure 5: Physical Insecurity

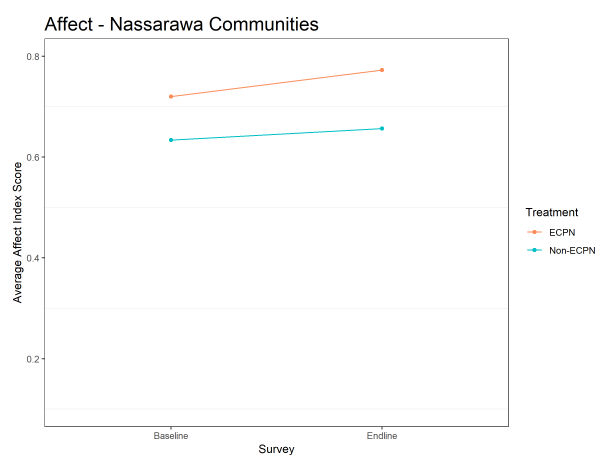

Figures 5a and 5b show the descriptive change in insecurity for treatment and control communities. The insecurity of control communities declines slightly from baseline to endline but insecurity in treatment communities declines substantially more. Treatment communities initially felt more insecure than control communities but were more secure at the end of the program. The intervention substantially improved the security of people in intervention communities.

5.4 Exploring these effects: state-level differences

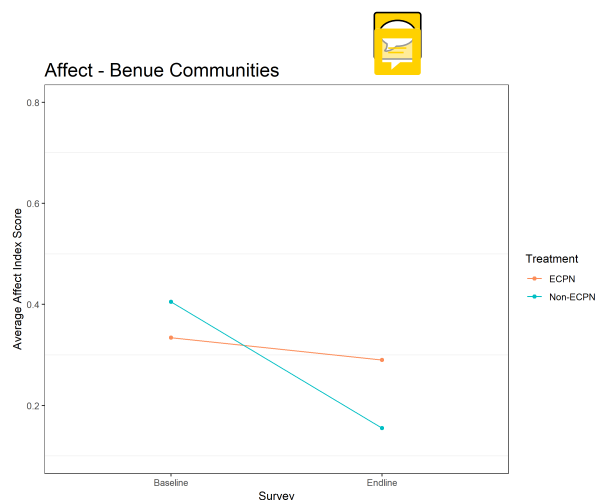

We note that some of our findings are due to outcomes worsening in control sites rather than improving in treatment sites. To understand these trends in greater depth, we explored state-level differences. We chose to look at state-level differences because Benue experienced an exogenous shock before the endline survey that may explain worsening outcomes in the control group. Benue, which always suffered more violent

conflict than Nassarawa, enacted an anti-grazing law making it illegal for pastoralists to graze animals outside of fenced in areas. This law led to violence and a migration of pastoralists out of Benue and into surrounding states, like Nassarawa. State-level differences in the effectiveness of the intervention tell us about the effects in these differing contexts. This study is not powered to detect statistical differences between treatment and control groups within Nassarawa and Benue, but we can look descriptively at differences between treatment and control group's within each state.

Affect: The overall analysis above suggested that the intervention increased intergroup affect despite a strongly negative secular trend. Figures 6a and 6b show baseline-endline changes for intergroup affect in Nassarawa and Benue, respectively. Disaggregating by state, we see that affect improved in treatment sites relative to control sites in both states. The overall secular trend is due to the sharp decline in Benue, where affect fell sharply in control sites while declining only slightly in treatment sites. In Nassarawa, affect improved modestly in both types of sites and increased most in treatment sites.

(a) Descriptive change in community-level intergroup affect from baseline to endline in Nassarawa. Red line is treatment site average, blue line is control site average. Moving up the Y-axis indicates improved affect between groups.

(b) Descriptive change in community-level intergroup affect from baseline to endline in Benue. Red line is treatment site average, blue line is control site average.

Figure 6: State-level intergroup affect

Contact: Figure 4a above suggested that the intervention increased contact despite the social environment leading to a sharp decline in control sites. Figures 7a and 7b show baseline-endline changes for intergroup contact in Nassarawa and Benue, respectively. The overall secular decline is likely due to the displacement in Benue, where intergroup contact went down for every group, though it declined far less in treatment sites. In Nassarawa, intergroup contact increased in both treatment and control sites, but far more in treatment sites. These results suggest that the intervention increased intergroup contact both in the context of a pastoralist exodus (Benue), and a pastoralists influx (Nassarawa). These patterns are unlikely to be floor and ceiling effects — eight of thirty communities reported contact higher than the 0.60 mean in Nassarawa, and seven of thirty communities reported less contact than the 0.08 mean in Benue. 0.08 and 0.60 are unlikely to be floor and ceiling when 50% of communities went beyond them.

(a) Descriptive change in community-level intergroup contact from baseline to endline in Nassarawa. Red line is treatment site average, blue line is control site average. Moving up the Y-axis indicates improved contact between groups.

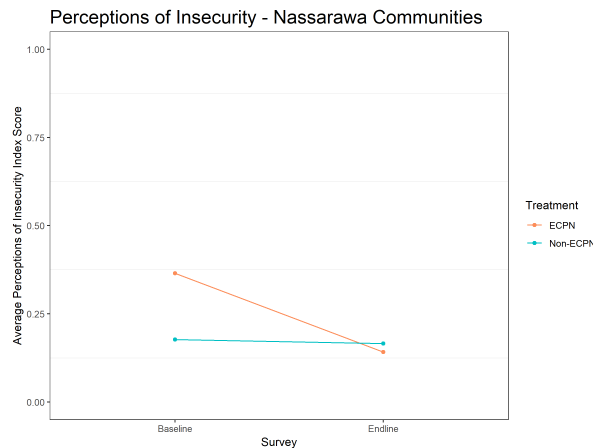

(b) Descriptive change in community-level intergroup contact from baseline to endline in Benue. Red line is treatment site average, blue line is control site average.

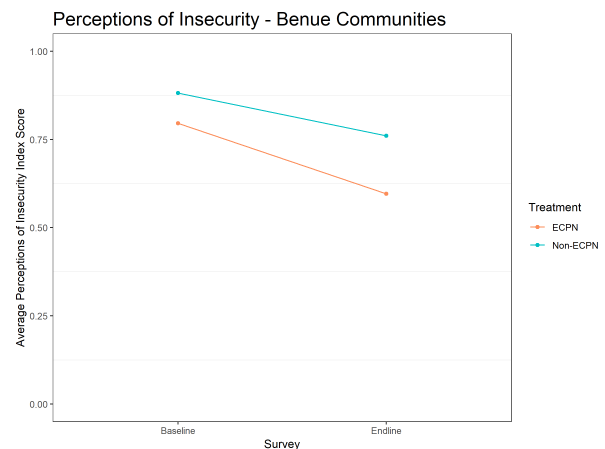

Figure 7: State-level intergroup contact

Insecurity: The overall analysis above indicated that insecurity declined much more in intervention sites than in control sites. Figures 8a and 8b show baseline-endline changes for insecurity in Nassarawa and Benue, respectively. Insecurity in Nassarawa treatment sites decreased substantially, while insecurity in Nassarawa control sites remained unchanged. Insecurity in both treatment and control sites in Benue decreased, but more so in treatment sites.

(a) Descriptive change in community-level insecurity from baseline to endline in Nassarawa. Red line is treatment site average, blue line is control site average. Moving up the Y-axis indicates improved security.

(b) Descriptive change in community-level insecurity from baseline to endline in Benue. Red line is treatment site average, blue line is control site average.

Figure 8: State-level perceived insecurity

5.5 Social desirability bias

To provide evidence that these survey results are due to intergroup contact and not due to social desirability bias, we analyze the effect of the intervention on attitudes about violence. Attitudes about violence are a good candidate for a “placebo outcome” because intergroup contact should not affect general attitudes about violence, but respondents may feel social pressure to answer violence questions in a desirable way.

If the intervention affects attitudes about violence, then we worry that other self-reports were affected by social desirability bias. If the intervention has no effect on attitudes about violence, then it is unlikely that other self-reports were affected by social desirability bias. We measure attitudes about violence with a six question index asking respondents if it is always, sometimes, rarely, or never justified to use violence in certain situations, such as retaliating against violence or bringing criminals to justice.

Figures 9a and 9b show baseline to endline changes in attitudes towards violence for the treatment and control groups. The intervention has no effect on attitudes about violence in the community-level data ($p=0.691$) or the individual-level data ($p=0.556$). The coefficients are negative in both cases, so this result is not due to a lack of statistical power. The lack of an effect on this “placebo” outcome, plus our use of survey experiments and behavioral observation to corroborate survey self-reports, suggests that our self-report results for primary outcomes are not due to social desirability bias. More details about the placebo analysis are available in Appendix C.

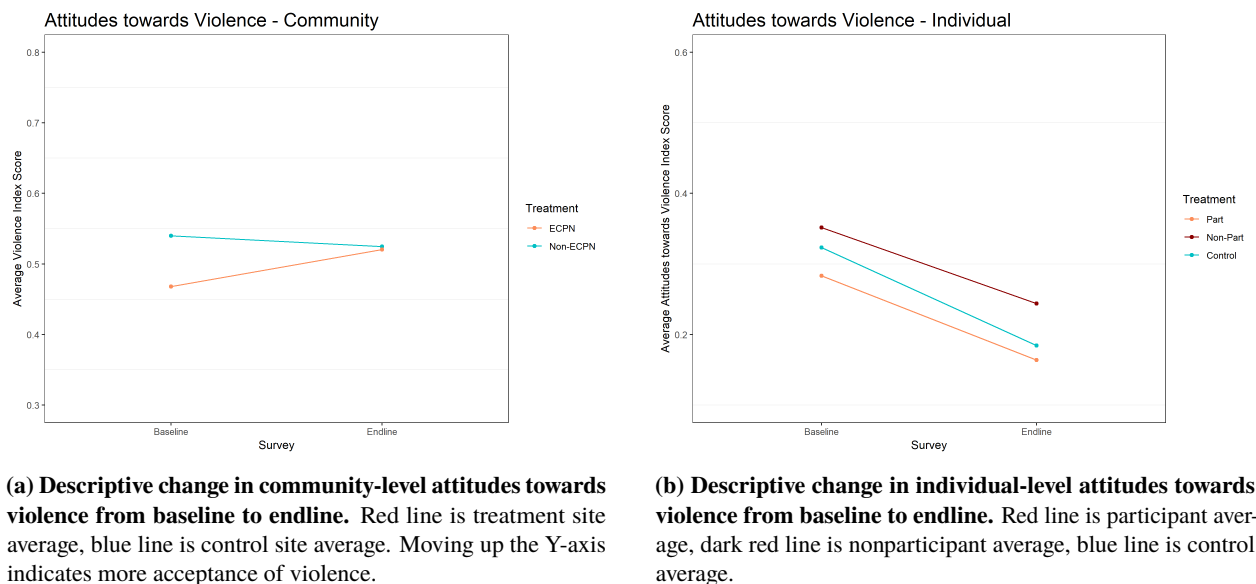

Figure 9: Social desirability check: attitudes towards violence

6 Discussion

This paper provides evidence that intergroup contact can improve intergroup relations, even in dire circumstances. We tested the effects of a programmatic contact intervention in an active and escalating conflict between farmers and pastoralists in Nigeria. The persistent violence of this context and personal involvement of the research participants poses a stringent test for contact to improve intergroup relations. The violence provides grievances that feed outgroup animosity, reinforce group differences, strengthen social and psychological barriers to improving attitudes, and support the perception that each groups’ interests are opposed. Despite the difficult context, the program improved intergroup affect, fostered more intergroup contact, and decreased feelings of insecurity in these communities.

This study also provides suggestive evidence that the effects of contact programs, which typically involve only a small subset of a community, can spillover to others in the community. Respondents from intervention communities who did not directly participate in our intervention felt more outgroup affect toward the other side and felt more physically secure from violence than control respondents, who were not exposed to the program at all. These attitudinal and perceptual changes cannot be explained by increased contact alone. While contact in treatment communities increased more than contact in control communities, contact by nonparticipant and controls respondents increased at the same rate while outgroup affect and perceptions

of physical security only increased for nonparticipants. As a result, we believe that some of the change in outgroup affect and perceptions of security are due to a spillover effect.¹⁸ By examining both direct and indirect participants, we are able to address a main critique of many contact-based and peacebuilding interventions: that even if these interventions change individuals, it is often not clear whether this change is scalable and will lead to societal change (Ditlmann, Samii, and Zeitzoff 2017).

We are not able to determine how this spillover from direct to indirect participants occurred, but we speculate that spillover occurred through three mechanisms that could shift people's perceptions of how the two groups can and should interact. First, nonparticipant community members may have observed members of both groups cooperate to address shared issues. The intervention established project committees of about 12-15 farmers and pastoralists, and other community members may have learned from their example. Second, some nonparticipants may have learned about the other side from personal interactions with participants. Third, and, we think, most importantly, the intervention may have caused knowledge about the other side and norms of cooperation to diffuse through each community. One of the goals of the intervention was to motivate norms and informal institutions that would impact the entire community and last beyond the intervention.

Our fieldwork suggests that communities learning about the other side assisted farmer and pastoralist leaders with mediating intergroup disputes, such as those caused by cows grazing on farmland. For example, our research partners on the ground noted that treatment communities were often able to resolve their disputes because pastoralists became more aware of the financial value of the crops destroyed by cows and farmers became more aware of the difficulty of controlling and corralling thousands of cows; no such learning occurred in control communities.¹⁹ The intervention could also have encouraged the formation of other informal institutions that support cooperation, like ingroup policing: ingroup members punishing other ingroup members who violate the rights of outgroup members (Ditlmann and Samii 2016; Fearon and Laitin 1996). As leaders and the project committees established intergroup cooperation, they may have publicly reprimanded ingroup members who spoke against the other side or did anything that would hamper the benefits of cooperation. Visible ingroup policing shows ingroup members that cooperation is the desirable action and shows outgroup members that they need not retaliate against the other side.

This paper also contributes to the growing number of field experiments testing contact theory. One of the major questions emerging from this literature is whether these interventions shift attitudes, behaviors, or both. While Scacco and Warren (2018) and Mousa (2020) find changes in behaviors but not attitudes, Paler et al. (2020) find changes in attitudes, but not behaviors. One difference between these interventions is whether the peacebuilding elements of the program were explicit or implicit. Like Paler et al. (2020), we test an explicit peacebuilding intervention. We find some changes in attitudes (e.g., outgroup affect) and some changes in behaviors (e.g., in contact—both self-reported and observational, but not in the public goods game). Unlike these other contact-based interventions which ranged from a one-shot meeting (Paler et al. 2020) to sixteen weeks (Scacco and Warren 2018), ours lasted two years. That we were able to provide a stronger “dosage” of contact may be one potential explanation why we were able to see changes in both attitudes and behaviors.

Another difference between these other studies and ours, and perhaps why we see a spillover effect, is the public nature of the contact. In these other studies—vocational training, sports and dialogues—the contact was contained and not broadcasted to the larger community. Our treatment was much more public, with community leaders holding open fora and the construction of community infrastructure as a result of joint project committees. Several recent studies suggest that public information has a greater impact on attitudes and behaviors than private information (Adida et al. 2020; Arias 2019; Grossman and Michelitch

¹⁸ Another possibility is that no spillover occurred, but rather nonparticipants benefited from the projects completed by the project committees. The project committees improved infrastructure useful to the farmer and pastoralist communities, which could have reduced resource-based drivers of conflict and influenced participants and nonparticipants. This is not spillover, though this is another way the intervention could have affected nonparticipants.

¹⁹ We are especially grateful to Israel Okpe for this and other observations about farmer-pastoralist conflict dynamics.

2018). In some cases, maintaining the confidentiality of contact is a necessary security measure, as was likely in the case of Christian and Muslim soccer players in Mosul (Mousa 2020). In those contexts, those who are willing to meet with the other side may be considered traitors and targeted by less tolerant ingroup members. However, by keeping the contact private, there are fewer opportunities to shift norms of appropriate and accepted behavior between groups. This could be one reason why we see behaviors change outside the confines of the intervention—increased contact in markets—while there is little evidence of a change in behaviors off the sports field in Mosul.

This study also points to an opportunity for collaboration between scholars of intergroup contact and scholars of conflict. These literatures are often concerned with the same end goal — reducing conflict — but rarely speak to one another. Conflict scholars often see conflict as a bargaining problem, and violence as a bargaining failure. The conflict literature points to a lack of trust as the primary cause of conflict and usually posits a strong third party actor as one effective way of guaranteeing peace. Intergroup contact research hints that intergroup contact can create cooperative norms and institutions that serve the same function as a strong third party. Improving relations — especially improving trust — through psychological interventions like intergroup contact can help groups overcome trust problems and reduce the likelihood of violence.

There remain several opportunities to learn about the effects of contact in conflict environments. First, this study employed a design to test the hypothesis that contact would improve group relations in an active conflict. Future studies can bring more causal evidence to the question of how contact improves group relations. For example, does contact make people more empathetic or able to take the perspective of the other group? Second, while we see evidence of spillover, we are unsure how it occurred. Future studies should examine how social norms and interpersonal discussion diffuse the positive effects of contact to other ingroup members without outgroup contact. Third, future work should more deliberately study the dosage of contact necessary to improve attitudes and behaviors.

Finally, contact interventions, explicitly or implicitly, involve the groups cooperating to achieve a joint goal. This intervention was designed to benefit all communities by having the conflicting communities cooperate successfully. But what if contact is not successful and the goal is not achieved? Does contact itself still improve attitudes, or does contact work because groups begin to associate cross-group cooperation with good outcomes? In a similar vein, are Allport's conditions necessary for contact to achieve its aims, or are they only needed insofar as they ensure the intergroup cooperation generates positive outcomes for both groups? Future studies should determine the necessity of Allport's conditions and attempt to differentiate the fact of contact from the outcomes that group cooperation produces.

7 Appendices

7.1 Appendix A: Randomization Inference and Bootstrapping

Randomization inference and bootstrapping are nonparametric methods to generate p -values (randomization inference) and confidence intervals (bootstrapping). With *randomization inference*, we first shuffle the treatment variable to break the relationship between treatment and outcomes. Next we regress outcomes on treatment using our regression equation and store the resulting coefficient. Lastly, we repeat that process 10,000 times to create the distribution of coefficients we would observe if treatment had no effect on outcomes — the null hypothesis. Our p -value is the proportion of the null distribution that is greater than or equal to our observed coefficient.

Bootstrapping for standard errors is similar, but instead of shuffling the treatment indicator we resample units with replacement. By resampling with replacement, we create the empirical distribution of our data and the range of possible treatment effects we might observe if we repeated the experiment 10,000 times. The treatment effect at the 2.5th percentile and at the 97.5th percentile are equivalent to a 95% confidence interval (Efron and Tibshirani 1994).

In each of these procedures, we mimic our randomization process by randomizing/resampling the intervention to communities in site-level clusters and within state blocks. This means that both communities in

an implementation site (farmers and pastoralists) will always be treated/sampled together and that assignment to the intervention and resampling are conducted separately in Nassarawa and Benue, just as the intervention was assigned in this study. This procedure ensures that our null distribution (for p -values) is created by randomizing the intervention between exchangeable units and that our empirical distribution (for confidence intervals) is created by resampling units as they were sampled.

7.2 Appendix B: Results with Additive Indices

These tables show results for self-report survey outcomes made with additive indices. The tables include the coefficients and p -values with additive indices for community- and individual-level analyses.

	ag_coef	ag_p	ind_coef	ind_p
Affect	0.093	0.037	0.062	0.056
Insecurity	0.015	0.174	0.030	0.011
Contact	0.054	0.193	0.070	0.143

Table 1: Effect of the intervention on main outcomes with additive indices. The first and second columns are coefficients and p -values for aggregate community-level analyses. The third and fourth columns are coefficients and p -values for individual-level analyses.

7.3 Appendix C: Mechanisms and Placebo Analysis

These tables show results for mechanism and placebo outcomes using inverse-covariance weighted indices. The tables include the coefficients and p -values for community- and individual-level analyses.

	ag_coef	ag_p	ind_coef	ind_p
Threat	-0.065	0.796	0.007	0.350
Empathy	0.129	0.089	0.127	0.010
Perspective-Taking	-0.040	0.640	0.029	0.195
Ingroup Expansion	0.036	0.252	0.016	0.166
Placebo (Violence)	-0.067	0.691	-0.007	0.556

Table 2: Effect of the intervention on mechanism and placebo outcomes. The first and second columns are coefficients and p -values for aggregate community-level analyses. The third and fourth columns are coefficients and p -values for individual-level analyses.

7.4 Appendix D: Endorsement Exp Plot

Figure 10 shows the descriptive results of the endorsement experiment.

Figure 10: Effect of outgroup endorsement on policy support for treatment and control sites. Red line is treatment site average, blue line is control site average. Moving down the Y-axis indicates decreased trust in other group.

7.5 Appendix E: Survey Questions

Outgroup Affect

- With regards to someone from [X GROUP], would you feel comfortable:
 - if they worked in your field?
 - paying them to watch your animals?
 - trading goods with them?
 - sharing a meal with them?
 - with a close relative marrying a person from [X GROUP]?
- From 1-5, how much do you trust people from [X GROUP] in your area?
- Now I'm going to ask you questions about your community here in Benue/Nassarawa, including [X GROUP]. Please tell me how strongly you agree/disagree with each of the following statements: People in this area can be trusted.

Contact

- Now I'm going to ask you questions about your contact with [X GROUP] in your area.
 - Think of the market you go to most frequently. During the past month, have members of X GROUP gone to that market too? In the past month, how many times did you interact with X group in the market?
- In the past month, have you:
 - Joined a member of X group for a social event outside the home? How often?
 - Hosted a member of X group for a ceremony in your home? How often?
 - Gone to the home of a member of X group for a ceremony? How often?

- Have you interacted with members of X group in any other way in the past month?

Insecurity

- In the last year were there any areas that you avoided going to or through because of insecurity during the night?
- In the last year were there any areas that you avoided going to or through because of insecurity, during the day?
- In the last year, did insecurity ever prevent you from:
 - Working when you wanted to work? About how many days were you unable to work?
 - Going to the market?
 - Getting water for the household?
 - Going to your field/farm?
 - Moving your animals to grazing areas?
 - Moving your animals to water?
 - Earning money or going to work?
 - Going to school?

Endorsement Experiment

- Imagine that there is a proposal by [**the Farmer's Cooperative Society/MACBAN**] for action to enhance access to clean water in rural areas. Though expensive, the proposal aims to bring fresh, clean water to hundreds of areas without access to it, including this one. If this were proposed, how would you feel about it?

Percent Experiemnt

- Think about groups that you might join in your leisure time. Would you join a group that had **5/25/50/75%** X Group members?
- Think about the community you live in. Would you live in a community that had **5/25/50/75%** X Group members?

Violence Placebo

- Now I am going to ask you some questions about the use of violence. Is it always, sometimes, rarely, or never justified to use violence to do each of the following:
 - Retaliate against violence
 - Defend one's group
 - Maintain culture and traditions
 - Defend one's religion
 - Bring criminals to justice
 - Force the government to change their policies

Threat

- Please tell me how strongly you agree/disagree with each of the following statements:
 - You see X group as a threat to your community
 - You think X group have too much influence on your community

- You think that people from X group have different morals than people from your group

Empathy and Perspective Taking

- Suppose something unfortunate happened to someone from X group in this community, such as a serious illness or the death of a parent. How likely is it that some people in the community from your group would get together to help them?
- Suppose something unfortunate happened to someone from your group in this community, such as a serious illness or the death of a parent. How likely is it that some people in the community from X group would get together to help them?
- Some people say [X GROUP] is responsible for most of the violence in this community, while others say that both groups are responsible for the violence here. Which is closer to your view?

Ingroup Expansion

- Now I'm going to ask you questions about your community here in Benue/Nassarawa, including X group. Please answer honestly and remember that your responses will remain confidential. Please tell me how strongly you agree/disagree with each of the following statements:
 - People in this area are willing to help their neighbors across ethnic and religious lines
 - People in this area can be trusted
 - People in this area generally do not get along together
 - People in this area do not share the same morals
 - People in this area see the benefits of working together to achieve common goals
 - What proportion of your group in this area contribute time or money toward common development goals, such as building a levy or repairing a road?
 - What proportion of X group in this area contribute time or money toward common development goals, such as building a levy or repairing a road?
 - If there was a water supply problem in this community, how likely is it that people from your group and people from X group would cooperate to try to solve the problem?

Public Goods Game

"Thank you very much for participating in our survey. Before I go, there is one last thing. As you may have heard, we have development funds to use in this community. We have randomly selected you as one of the 50 people to receive these funds. These funds are not for a Mercy Corps project, but rather for you to keep personally or to donate to a community fund.

We have 1,000 Naira to give to you. It is yours, and you can use it either way—for yourself or for a community good.

Your community and [joint farmer/pastoralist community] have created a project committee to whom you can donate this money so that it may be used to help both communities. The project committee has 4 people from each community. We have found a donor that will match the funds that you all contribute to the project committee, so that if you donate 100 Naira the project committee receives 300 Naira, and if you donate all 1,000 Naira the project committee receives 3,000 Naira. You are welcome to donate none, some, or all of the money to the project committee.

These are your individual donation envelopes. All the donations will be private – only you will know how much money you donated. It is essential that you keep how much you give private – please do not tell anyone. I have with me a donation envelope to collect donations. Please go into your home, put however much

of the 1,000 Naira you wish to donate to the project committee in the envelope, take whatever amount you want to keep for yourself, and come back to place your envelope in the donation envelope. Remember, you are welcome to donate none, some, or all of the money to the project committee. After that we are finished and you may continue your day. We will come back and publicly announce how much money your community's project committee will receive."
